METHOD OF PRODUCING CHARCOAL, *CONDITIONED FUEL GAS AND*
POTASSIUM FROM BIOMASS

CONTINUATION - IN - PART

This is a Continuation - in - Part application pending from Patent Application 10/254950 to Fred P. Beierle and entitled METHOD OF PRODUCING CHARCOAL FROM BIOMASS. New matter added at the filing of this Continuation-In-Part application is shown in italics and includes materials inserted at the Field of the Invention, Brief Description of the Drawings, Detailed Description and Claims. Addressed principally are factors relating to the production and processing of fuel gas produced from the charcoal production process of the parent, for use in combustion engines. Disclosed here is a process of preparing fuel gas from the charcoal production apparatus and process, described in the parent and as seen herein, for use in diesel engines or any combustion engine.

Field of the Invention

This invention relates to the production of charcoal and fuel gas for combustion engines. More particularly, this invention relates to the maximization of charcoal production with the production of fuel gas as a secondary consideration. Fuel gas is conditioned for use in combustion engines. The parent application is abandoned with the filing of this Continuation-in-Part application.

Background of the Invention

This invention relates generally to the art of producing charcoal, and secondarily fuel gas, from organic material, and more particularly concerns an apparatus and method in such art which is self-sustaining in operation.

The use, per se, of a pyrolysis process to convert organic material, such as wood chips, to charcoal and fuel gas is well known, and a wide variety of devices

1 have been designed to accomplish such a result. A primary disadvantage of such
2 devices, including those generally referred to as gasifiers, is that a substantial
3 produced charcoal is substantially consumed. A recognized by-product of the
4 pyrolysis process is tar, which affects both the operation of a gasifier and the end use
5 apparatus of the produced fuel gas, such as an internal combustion engine or other
6 burner. The production of tar is discussed in U.S. Pat. No. 4,268,275 and U.S. Pat.
7 No. 4,421,524 both to Chittick and U.S. Pat. No. 4,530,702 to Fetters et al. The
8 solution regarding tar, disclosed in these patents, included a reaction chamber having
9 a pyrolysis zone followed by a reaction zone comprising a bed of charcoal heated to a
10 high temperature. The high temperature of the charcoal and the catalytic effect of the
11 ash residue on the surface of the hot charcoal break down the tars from the pyrolysis
12 zone into carbon monoxide and hydrogen. The heat for the pyrolysis zone and the
13 reaction zone was provided externally. The issue of minimizing the consumption of
14 charcoal is not addressed. U.S. Pat. No. 4,530,702 to Fetters et al additionally
15 disclose the introduction of steam for increased fuel gas production. The introduction
16 of steam is counterproductive vis-a-vis the production of charcoal increasing the
17 production of carbon fines and production of ash, both having little or no value.

18 Also noted herein are U.S. Patents to Brioni et al, 5,725,738; to Koslow,
19 5,946,342 and 6,061,384; and Nagle et al, 6,051,096 and 6,124,028.

20 The patents referred to herein are provided herewith in an Information
21 Disclosure Statement in accordance with 37 CFR 1.97.

22

23

Summary of the Invention

24 The present invention includes a process for producing charcoal, and
25 secondarily fuel gas, from organic material, in which a charge of charcoal is initially
26 present in a pyrolysis reaction chamber, thus forming a charcoal bed therein, the
27 process being self-sustaining so that it does not require the addition of external heat
28 following initiation of the process, wherein the process comprises the steps of:
29 igniting a portion of the charcoal bed within the pyrolysis reaction chamber, the
30 ignition being substantially uniform over the cross-sectional area of the charcoal bed;
moving air through the charcoal bed so that the portion of ignited charcoal becomes

1 sufficiently hot to create a pyrolysis reaction zone in the charcoal bed; adding organic
2 material, typically in the form of pellets or chips or the like, to the reaction chamber
3 on top of the charcoal bed; forming a head of raw unreacted fuel; and establishing
4 and maintaining a zone in the pyrolysis zone in which the combustion is
5 homogeneous, the zone of homogeneous combustion extending over the entire
6 cross-sectional area of the pyrolysis zone. In addition, the steps of igniting, removing
7 charcoal and adding biomass, and with and without the steps of establishing and
8 maintaining, the step of directing additional air into the charcoal from beneath the
9 charcoal bed is added, providing a capability to maximize the production of charcoal
10 and minimize the consumption of charcoal within the apparatus. Disclosed herein is
11 the production of charcoal in a charcoal production bed in a single reaction chamber
12 the production bed comprising in sequence (a) an upper layer of biomass input
13 material, (b) an intermediate pyrolysis zone layer in which the input material is
14 reduced to devolatilized char and pyrolysis volatiles comprising hydrogen, carbon
15 monoxide, methane, nitrogen, water vapor and tars, the intermediate layer being at a
16 temperature within the range of 800 degrees C. to 1000 degrees C., and (c) a lower
17 layer comprising substantially only hot charcoal. The gases produced are generally as
18 follows as a percentage of total gas produced: Hydrogen 17-18%; Carbon Monoxide
19 38%; Methane 2%; with the remainder primarily Nitrogen with some trace gases also present.

20 Secondarily, the present invention includes an apparatus for converting a
21 biomass input to an output gas which is suitable for use as a fuel gas, wherein the
22 apparatus includes a reaction chamber which is open at its lower end, in which, in
23 operation, a bed of charcoal is present in which in turn is located a pyrolysis reaction
24 zone. The pyrolysis reaction converts the biomass input into fuel gas volatiles and
25 charcoal. Air is drawn down through the reaction chamber from above the pyrolysis
26 zone and fuel gas exits from the apparatus. In contrast to prior art, there is no
27 provision for additional air to be directed into the charcoal bed from below the bed.
28 Such lessens the production of charcoal and operates to the detriment of the purposes
29 of this invention.

30 Control and instrumentation includes a control motor drive of an auger means
for removal of charcoal having instrument means to detect quantities of charcoal to

1 be removed and a control means, including valve means, for use on fuel gas output
2 lines which includes a pressure sampling means for sampling the gas pressure in the
3 output line; control means including control valve means positioned in a return line
4 which, when open, permits recirculation of a portion of the gas in the output line; and
5 control means responsive to the pressure in the output line, as sampled by the
6 sampling means, e.g., pressure transducers having an input to a control valve means,
7 to open the normally closed valve means when the pressure rises above a
8 predetermined value. Control and instrumentation means include but are not limited
9 to temperature, pressure, level or height and other control and measurement means
10 which may be accomplished, as recognized by those of ordinary skills in the control
11 and measurement arts, with thermocouple and other temperature measurement
12 instruments, pressure transducer and other pressure measurement instruments, stress
13 gages and other stress measurement instruments, light detectors and limit switches
14 and other level measurement instruments having controller inputs to controllers for
15 valve, process and other control functions as are commonly recognized by those of
16 the instrumentation and control arts.

17 *Combustible fuel gas is a by-product of the charcoal production described in*
18 *the parent application. Fuel gas is discharged to a heat exchanger, a demister, a fuel*
19 *conditioner and to either storage or combustion in an engine means. A by product of*
20 *the heat exchanging process is water containing potassium usable as an agricultural*
21 *fertilizer.*

22

23 Brief Description of the Drawings

24 The foregoing and other features and advantages of the present invention will
25 become more readily appreciated as the same become better understood by reference
26 to the following detailed description of the preferred embodiment of the invention
27 when taken in conjunction with the accompanying drawings, wherein:

28 FIG. 1 is a cross-sectional diagram of the invention showing a charcoal
29 production bed (10) in a single reaction chamber (30) where the production bed (10)
30 comprises in sequence (a) an upper layer (13) of biomass input material, (b) an
intermediate layer (14) pyrolysis zone layer in which the input material is reduced to

1 devolatilized char and pyrolysis volatiles comprising hydrogen, carbon monoxide,
2 water vapor and tars, the intermediate layer being at a temperature within the range of
3 800 degrees C. to 1000 degrees C., and (c) a lower layer (15) comprising substantially
4 only hot charcoal, the hot charcoal being at a temperature which is sufficiently high to
5 reduce any tars from the pyrolysis zone layer to carbon monoxide and hydrogen; the
6 charcoal production bed having an outlet means (43) for fuel gas. The reaction
7 chamber (30) receives air input (50) at the upper layer (13). Seen is removal means
8 (45), seen here as an auger, for removal of charcoal.

9 FIG. 2 is a flow diagram of the invention of FIG. 1.

10 FIG. 3 is a flow diagram showing the fuel gas output (44) from the invention
11 of FIG. 1. Illustrated is the introduction of hot fuel gas (44) into a heat exchanger
12 means (60) and into a water or coolant reservoir (65) with the exhaust of the cooled
13 fuel gas seen as output from water or coolant reservoir (65) directed to a demister
14 means (80) followed by directing the demister output (82) to a fuel conditioner means
15 (100) where said fuel conditioner output (130) is stored or combusted in an engine
16 means (140).

17 FIG. 4 and FIG. 5 illustrates details 4 and 5 from FIG. 3 showing an aspect
18 of the fuel conditioner means (100).

19 Fig. 6 illustrates a detail from Fig. 3 showing the funnel means (200) having a
20 slope, θ (210) at the funnel side (220), relative to a vertical, and of the charcoal
21 discharge funnel means (230) having a slope, θ (240) of charcoal discharge funnel
22 slope (240) relative to a vertical where the slope will be greater than approximately
23 45 degrees and are preferred at approximately 60 degrees and showing that both the
24 funnel means (200) and the charcoal discharge funnel means (230) are primarily
25 inverted conical in structure.
26

27 Detailed Description

28 FIG. 1 shows the preferred embodiment of the present invention, which in
29 operation is self-sustaining, in that it requires no external heat source to maintain
30 operation. The reaction chamber (30) may be composed of heat and corrosion

1 resistant materials including, for example, fiber-ceramic insulating material, lined
2 interiorly with unreactive inconel or stainless steel metal, either of which resist attack
3 from oxygen. In the preferred embodiment the reaction chamber will have a circular
4 cross-section but may be formed with a variety of cross-sections. Those of ordinary
5 skills in the heat and corrosion arts will appreciate other materials suitable for the
6 reaction chamber (30).

7 In the preferred embodiment diameter of the reaction chamber (30) is
8 substantially uniform along its length, except for the uppermost portion or upper layer
9 (13), which may be slightly flared to accommodate a head of biomass (20) which may
10 be comprised, for example, of fuel pellets, vegetable matter and other organic matter
11 as will be appreciated by those of ordinary skill in the art. Biomass (20), in the
12 preferred embodiment is delivered by delivery means (16) into the reaction chamber
13 (30) by an motor controlled auger (16). In the preferred embodiment a light detection
14 means, provided in the preferred embodiment as a electric eye (22), is mounted by
15 mounting means at a top (31) of the reaction chamber (30). The electric eye (22) set
16 provides a switch function electrically communicating with a motor drive for the
17 motor controlled auger (16) causing power to the motor controlled auger (16) when
18 the electric eye (22) detects the absence of biomass. Delivery means (16) may
19 include hoppers, conveyors, augers and other such feed or delivery devices. The
20 preferred embodiment for delivery means (16) is by motor controlled auger (16).

21 FIG. 1 is a cross-sectional diagram of the invention showing a charcoal
22 production bed (10) in a single reaction chamber (30) where the production bed (10)
23 comprises in sequence (a) an upper layer (13) of biomass input material, (b) an
24 intermediate pyrolysis zone layer (14) in which the input material is reduced to
25 devolatilized char and pyrolysis volatiles comprising hydrogen, carbon monoxide,
26 water vapor and tars, the intermediate layer being at a temperature within the range of
27 800 degrees C. to 1000 degrees C., and (c) a lower layer (15) comprising substantially
28 only hot charcoal, the hot charcoal being at a temperature which is sufficiently high to
29 reduce any tars from the pyrolysis zone layer to carbon monoxide and hydrogen; the
30 charcoal production bed (10) having an outlet means (43) for fuel gas. Seen is
charcoal removal system (40) comprised of removal means (45), shown for example

RECEIVED
MAR - 1 2007
FISHING SERVICE
DIVISION

1 as an auger but which may be provided by a valve controlled chute, screw drive and
2 other lift or moving devices; also seen as a part of a removal system (40) is the
3 conveyance or routing means (34) and charcoal storage means (36).

4 Control of removal means (45) is effected by temperature sensing means, e.g.,
5 thermocouples or other recognized temperature sensing devices, positioned in the
6 reactor chamber (30) where the temperature sensing means has an output received by
7 a controller for a delivery means (16). In the preferred embodiment temperature
8 sensing means is provided by at least one thermocouple (24) at the upper layer (13)
9 and in the preferred embodiment by one or a plurality of thermocouples (24), e.g., in
10 the preferred embodiment by three thermocouples (24) positioned respectively at the
11 upper layer (13), intermediate layer (14) and at the delivery means (16). In the
12 preferred embodiment a thermocouple positioned in the reactor chamber (30) at the
13 intermediate layer (14) will detect a temperature change indicating the rising of the
14 pyrolysis zone and will provide switch means for the control of a motor controlled
15 auger removal means (45) to move the intermediate layer (14) down in the reaction
16 chamber (30); a thermocouple at the top (31) of the reaction chamber (30) will
17 provide high temperature information for safety shutdown of a fuel gas pump (42)
18 thereby terminating air flow and the operation of the system; a third thermocouple at
19 the delivery means (16) provides additional high temperature sensing and safety
20 control for pump (42) control. Circuit interconnections from one or a plurality of
21 thermocouples to controllers are not shown and are not claimed herein as inventive
22 elements of this disclosure.

23 It is noted that the charcoal moved from the lower layer (15) will be may be in
24 the range of 600-700 degrees F. Hence this removed charcoal must be contained in
25 an environment which is essentially oxygen free, lest it combusts, until it has cooled.
26 Conveyance or routing means (34) may be auger via piping, conveyor or other such
27 device. Eventual charcoal storage, not shown, may be, for example, bins, trucks, and
28 other such containers suitable for storage or transport to a processing facility.

29 Prior to initiation of operation, the reaction chamber (30) lower layer (15) is
30 filled with devolatilized charcoal. The devolatilized charcoal is substantially uniform
in size and configuration, although the particular size of the charcoal will depend to

1 an extent on the size of the reaction chamber. The lower layer (15) of the charcoal
2 production bed (10) is then ignited, typically, but not necessarily, at or near the lower
3 layer top (33) thereof by ignition means, e.g., a torch, electric start, or similar device.
4 Following ignition of the lower layer top (33), biomass (20) is added forming the
5 upper layer (13) and atmospheric air (50) is moved downwardly through the reaction
6 chamber (30) and production bed (10) by means of a pump (42) which is typically
7 located in fuel gas outlet means (43) line so that air (50) is drawn into and through the
8 reaction chamber (30) from the atmosphere above the reaction chamber (30) in that
9 the pressure in the reaction chamber (30) is less than atmospheric. The intermediate
10 layer (14) forms the pyrolysis zone as air (50) is drawn through the production bed
11 (10). Alternatively, a source of pressurized air may be used at the top (31) of the
12 reaction chamber (30) to force air (50) through the reaction chamber (30) and out the
13 outlet means (43).

14 It is important for tar-free operation of the invention that the combustion
15 reaction in the pyrolysis zone be substantially homogeneous over the cross-sectional
16 area of the reaction chamber (30). This means that the temperature profile across the
17 pyrolysis zone (14), over the cross-section of the reaction chamber (30), should be
18 substantially uniform, so that there are no hot spots or channels in the pyrolysis zone
19 (14). Maintaining a homogeneous intermediate layer (pyrolysis zone) (14) results in
20 the intermediate layer (14) being relatively thin, no matter what the size of the
21 reaction chamber (30). Any tars which are produced in such an intermediate layer
22 (14) are rather light in weight and are completely broken down by the hot lower layer
23 (15) charcoal bed below the intermediate layer (14).

24 The pyrolysis reaction is homogeneous in the preferred embodiment shown
25 largely because the airflow through the reaction chamber (30) is substantially uniform
26 over the cross-sectional area of the chamber (30), particularly over the pyrolysis zone
27 (14). Thus, a uniform pressure exists over the cross-sectional area of the chamber
28 (30) in the embodiment shown. To insure that this occurs, the structure by which air
29 (50) is provided to the reaction chamber (30) should not be such as to channel air into
30 the reaction chamber (30), such as occurs with tuyeres, for instance. Air (50) must be
permitted to disperse evenly over the top (31) of the biomass (20) raw fuel head upper

1 layer (13) and to be drawn down uniformly through the head or upper layer (13).
2 Further, the size of both the biomass (20) particles, and the charcoal in the lower
3 layer (15) of the charcoal production bed (10) should be somewhat uniform in size.
4 Excessive "input dust", i.e., more than 10%-25% or so, comprised, for example of
5 fine biomass (20) particles, will likely have a detrimental affect on the operation of
6 the invention. Uniform biomass (20) particle size helps to insure a uniformity of
7 airflow through the chamber (30), at least over the cross-sectional area of the
8 intermediate layer (14). This in turn assists in maintaining a uniform temperature
9 profile over the cross-sectional area of the reaction chamber (30) in the vicinity of the
10 intermediate layer (14), which minimizes localized hot spots and/or channels in the
11 intermediate layer (14), thus resulting in a homogeneous combustion of the biomass
12 (20) throughout the intermediate layer (14).

13 It should be understood that additional techniques, perhaps involving screens
14 or other gas dispensing devices, may be used to insure uniformity of airflow through
15 the chamber and a uniform temperature profile. Further, although atmospheric air has
16 been used as an example of the gas which is moved through the chamber, it should be
17 understood that other gases, including oxygen-enriched atmospheric air, or pure
18 oxygen, could be used.

19 The establishment of a intermediate layer (14) with homogeneous combustion
20 may be assisted by a biomass leveling means (52) provided for example by a cone
21 (52) fixed by cone affixing means at reactor chamber top (31). Prior art demonstrated
22 stirring of the lower layer (15) of the charcoal production bed (10) following ignition.
23 It is seen that stirring degraded the charcoal into fines and is counterproductive to the
24 production of charcoal of usable particle size. As mentioned above, the resulting
25 intermediate layer (14) is relatively thin, regardless of the size of the reaction
26 chamber (30), and has a temperature of approximately 900.degree. C. Typically, the
27 time necessary for uniform ignition of the lower layer (15) of the charcoal production
28 bed (10), and for establishment of the intermediate layer (14), is very short, i.e. a few
29 minutes. After the intermediate layer (14) has been established, biomass (20) is fed
30 into the reaction chamber (30), into the area of the intermediate layer (14) on top of
the lower layer (15), so that three zones are established in the chamber; specifically,

1 the thin, hot intermediate layer (14) between the head of cool, unreacted biomass (20)
2 at the upper layer (13) and the lower layer (15).

3 The biomass (20) particles, once they reach the intermediate layer (14), are
4 reacted by the high temperature to produce charcoal and essentially tar-free fuel gas.
5 The temperature of the exiting gas is typically 50.degree. C. to 100.degree. C. below
6 the temperature of the intermediate layer (14), depending on radiation losses. The fuel
7 gas is essentially tar-free because there are no localized inhomogeneities in the
8 combustion in the intermediate layer (14), such as hot or cool channels, through
9 which the tars from the biomass (20) particles could otherwise escape and combine
10 into heavy tars. With homogeneous combustion in the intermediate layer (14), any
11 tars emanating from the biomass (20) particles are light, and the tar molecules are
12 small. These light tars, in the absence of channels or a long intermediate layer (14)
13 are then reacted by the catalytic action of the hot charcoal bed to form carbon
14 monoxide and hydrogen. Thus, the gas output of applicant's invention is reliably
15 tar-free.

16 As the biomass (20) particles move through the intermediate layer (14),
17 which is typically at a temperature of approximately 900.degree. C. but which can
18 operate effectively over a temperature range of 750.degree. C. to 1000.degree. C.,
19 fuel gas is produced and a devolatilized char is left behind. Thus, the boundary line
20 between the intermediate layer (14) and the lower layer (15) is where the biomass
21 (20) particles have been reduced to devolatilized char.

22 After a short period of operation, the temperature of the lower layer (15)
23 becomes quite hot, typically in the range of 800.degree. C. to 950. degree. C. Any tars
24 which do escape from the intermediate layer (14), which are light, as explained
25 above, are broken down by passage through the hot lower layer (15) of the charcoal
26 production bed (10) with resulting fuel gas exiting through outlet means (43) line.
27 However, inhomogeneities in the intermediate layer (14) result in the volatilized
28 gases polymerizing into large, heavy molecules forming clinkers. Additionally,
29 where biomass (20) of high silica content is used, the operating temperature of the
30 intermediate layer (14) should be controlled to the lower area of the temperature
range at about 800 degrees C. Clinkers are particularly susceptible to formation

1 where the biomass (20) is largely comprised of sclicia including grasses, straw and
2 hay. Where such biomass (20) is used temperature control is critical. Temperature
3 control in the preferred embodiment is by manual control of the pump (42). Those of
4 ordinary skill will recognize that temperature sensing and valve control is readily
5 available in the industry. Ash and other fines which are created by the operation of
6 the system of the present invention are carried out with the gas and removed by filter
7 (41), which is in the preferred embodiment is a bubbler tank comprised of a tank of
8 water through which the fuel gas is "bubbled". The filter (41) may, for instance, be a
9 cyclone separator and other separator or filtering means as recognized by those of
10 ordinary skill in filtering arts..

11 Because the intermediate layer (14) is relatively thin, and substantially
12 homogeneous in reaction, ignition and initiation of operation of the gasifier may be
13 accomplished rapidly, typically much faster than with conventional gasifiers. The unit
14 is also very responsive to changes in demand. The volume of fuel gas (44) output
15 from the gasifier is proportional to the quantity of air (50) flow through the unit, as a
16 change in the air-flow causes a corresponding change in the rate of biomass (20) fuel
17 consumed, and hence, the amount of gas (44) produced.

18 Another advantage of the homogeneous intermediate layer (14) described
19 above is that the unit is stable in operation, i.e. it produces a usable, tar-free gas (44)
20 output over a relatively wide range of input and output demands. Various kinds of
21 material may be used as biomass (20) input, including wood, straw, and other organic
22 materials, as long as the above size and configurational requirements are observed.
23 The unit is to an extent self-correcting in operation. If an inhomogeneity occurs,
24 additional heat will typically be produced in the vicinity of that inhomogeneity. The
25 additional heat then disperses over the entire intermediate layer (14), tending to
26 disperse the inhomogeneity.

27 The homogeneity of the reaction of the intermediate layer (14), including the
28 substantially uniform temperature profile, contributed to by the substantial uniformity
29 in size and configuration of the biomass (20) and the uniformity in air (50) flow over
30 the cross-sectional area of the reaction chamber (30), substantially eliminates hot spot
channels which characterize the operation of previous gasifiers. Any tars generated

1 in the intermediate layer (14) of the gasifier disclosed herein, are lightweight, small
2 molecules, as described above, and are broken down in a catalytic reaction by contact
3 with the devolatilized charcoal in the hot charcoal bed.

4 Even with a homogeneous radiation condition over the cross-section of the
5 intermediate layer, however, the gasifier can be over-driven to the extent that
6 channels are created in the pyrolysis zone and the charcoal production bed (10),
7 resulting in tars and clinkering. Thus, the velocity of the air (50) moving through the
8 unit is important to proper operation of the gasifier. In some instances, the gasifier is
9 more tolerant of differences in size of the biomass (20), when the air (50) velocity is
10 low. As the velocity of the air (50) increases, size uniformity of the biomass (20)
11 input becomes more significant. The inventors have found that a velocity of 0.27
12 cubic ft. of air per minute per sq. inch of cross-sectional area provides a good output
13 without overdriving the unit. A reasonable range of air (50) velocity including the
14 above value will provide satisfactory results.

15 With certain kinds of biomass (20) input, the relative dimensions of the three
16 zones will remain substantially stable within the chamber (30), with the consumption
17 of charcoal occurring at approximately the same rate as char is produced from the
18 fuel pellets in the pyrolysis zone. Such a circumstance is undesirable relative to the
19 goal of charcoal production. With most types of biomass (20) fuel inputs, such as dry
20 wood pellets, more charcoal will be produced by the pyrolysis reaction than is
21 consumed in the charcoal bed. In such a case, the level of the charcoal bed gradually
22 rises, raising the pyrolysis zone. At some point then, charcoal must be removed from
23 the chamber if proper operation is to continue. The excess charcoal can be removed
24 in a number of ways, either mechanically, or by changing fuel to one with a high
25 moisture content so that more charcoal is consumed than is produced by pyrolysis, or
26 by the addition of water or steam to the reaction chamber.

27

28 *Figure 3 illustrates the process of conditioning fuel gas (44) for consumption*
29 *in a combustion engine or for storage. The Fuel Gas (44) output is approximately*
30 *1000 degrees F. Disclosed here is the conditioning of the fuel gas (44) for use in a*
combustion engine. Hot fuel gas (44) is directed into a heat exchanger means (60)

1 *having water or coolant supply inlet (67) and water or coolant discharge (69). Heat*
2 *exchanger means (60), in the preferred embodiment is the direction of the hot fuel*
3 *gas (44) into a heat exchanger tank (60) containing water (65) wherein the hot fuel*
4 *gas (44) bubbles through the water (65) to be exhausted from the heat exchanger*
5 *tank (60) at a heat exchanger tank exhaust (71). Heat exchanger means (60) may be*
6 *supplemented by a supplemental heat exchanger means (62) comprising structure*
7 *from generally recognized heat exchanger means including but not limited to a tube*
8 *heat exchanger wherein the hot fuel gas (44) is received into a supplemental heat*
9 *exchanger means (62) which is positioned within the heat exchanger tank (60) and is*
10 *in fluid contact with the heat exchanger tank (60) contents, including as indicated in*
11 *this application, water (65) with the cooled fuel gas (44) then exhausted at a heat*
12 *exchanger tank exhaust (71). Those of ordinary skills in the heat exchanger arts will*
13 *recognize other heat exchanger structures equivalent to a tube heat exchanger.*

14 *The output from the heat exchanger tank exhaust (71) is a combination of*
15 *water vapor and fuel gas (44) and is directed then into a demister means (80) at a*
16 *demister input (81). The demister means (80) accumulates some portion of the water*
17 *vapor by condensation forming condensate (83). In the preferred embodiment the*
18 *demister means (80) is comprised of the input via at least one tube (81) and, as is*
19 *represented in Fig. 3, a flow diagram, a plurality of tubes 1...n (81) or other*
20 *equivalent means with the condensate (83) accumulated in the demister means (80)*
21 *and with the condensate (83) periodically drained from the demister means (80) by a*
22 *condensate drain means (84) comprised generally of a valve and piping means*
23 *discharging into a reservoir or other place for discharge of the condensate (83). The*
24 *fuel conditioner means input (110), is then directed through bubble forming means*
25 *(115) into and through a fuel conditioner means (100) containing fuel means (120).*
26 *Bubble forming means (115) is provided, in the preferred embodiment, by directing*
27 *the fuel conditioner input means (110) via pipe or tube means (110) to and through a*
28 *grid (116) formed of fine wire mesh or a plate with at least one aperture (117) as is*
29 *seen in Figures 4 and 5. Fuel means (120) includes but is not limited to diesel,*
30 *peanut oil, vegetable oils and other combustible substances as will be recognized by*
 those of ordinary skill in the arts as combustion engine fuels. The fuel conditioner

1 *output (130) will be a mixture of fuel gas (44) and fuel means (120) which is*
2 *exhausted via pump means (140) exerting a vacuum at the fuel conditioner output*
3 *(130). Fuel conditioner output (130) is directed to a storage or combustion at an*
4 *engine means (160).*

5 *Valve means, not shown in Figure 3, controls the water or coolant supply*
6 *inlet (67) and water or coolant discharge (69) and the condensate drain (84). Pipe*
7 *or tube means (75) provides fluid communication from fuel gas (44) input to heat*
8 *exchanger means (60), between heat exchanger means (60) and demister means (80);*
9 *between demister means (80) and fuel conditioner means (100) and between fuel*
10 *conditioner means (100) and storage or engine means (160).*

11 *The fuel conditioner output (130), a mixture of fuel gas (44) and fuel means*
12 *(120), will be, in the preferred embodiment, in the range of 5% to 20% diesel with the*
13 *balance comprised of fuel gas (44). With a combination of approximately 3.8%*
14 *diesel and 96.2% fuel gas (44), substantial pinging has been experienced. It has*
15 *been noted that controlled delivery of diesel, to the cylinders of a diesel engine,*
16 *lessens or stops pinging when each cylinder receives the same diesel concentration in*
17 *the fuel gas (44) and fuel means (120). Operation of diesel engines is difficult when*
18 *the diesel concentration in the conditioned fuel gas (44) is below 5% diesel. The*
19 *preferred embodiment of the output of the fuel conditioner output (130) will be with*
20 *diesel in the range of 5% to 10% and fuel gas (44) at 95% to 90%. The use of diesel*
21 *and fuel gas (44), forming the conditioned fuel gas (130) requires lower compression.*

22 *The conditioned fuel gas (130), as fuel for diesel engine means (160),*
23 *eliminates the need for fuel injectors due to the diesel content of the conditioned fuel*
24 *gas (130). Testing demonstrates that the conditioned fuel gas (130) also functions*
25 *with spark ignition combustion engine means (160). Use of the conditioned fuel gas*
26 *(130) with diesel engine means (160) also eliminates the need for glow plugs for*
27 *ignition when the ratio of diesel is increased in the conditioned fuel gas (130).*
28 *Alternative operations may commence with the starting of the engine means (160)*
29 *with traditional fuels with injection and glow plug means, with injection and glow*
30 *plug mean deactivated when the conditioned fuel gas (130) is introduced. The*
 conditioning with diesel, at the fuel conditioner means (100) also acts to remove tars

1 which may be transferred with the fuel gas (44). The conditioned fuel gas (130) may
2 be introduced directly into the engine intake manifold.

3 The water or coolant discharge (69) where the coolant is water, is found to
4 have concentrations of chemicals supportive of increased growth of plants. It is
5 understood that the chemicals introduced into the water or coolant discharge (69)
6 includes potassium. Experimentation has demonstrated increased growth of plants
7 when watered with the water or coolant discharge (69).

8 It is noted, by reference to Figure 6 as a detail from FIG. 1, in the process of
9 producing charcoal and fuel gas, that the upper layer (13) at a upper layer center
10 (12) may tend to drop in level relative to the upper layer (13) proximal a reaction
11 chamber wall (32) and proximal the top (31). Introduction of biomass (20) into a
12 funnel means (200), will direct biomass (20) toward the upper layer center (12)
13 thereby reducing the tendency of dropping in level at the upper layer center (12). A
14 similar obstructing event occurs at the discharge of charcoal from the lower layer
15 (15) to the charcoal removal system (40). The charcoal from the lower layer (15)
16 falls into the charcoal removal system (40) and tends, toward the walls of the
17 charcoal removal system (42) to stack and not readily advance toward the removal
18 means (45). The introduction of a charcoal discharge funnel means (230)
19 intermediate the lower layer (15) and the removal means (45), directs the charcoal
20 away from the walls (42) of the charcoal removal system (40) and toward the
21 removal means (45). The slope, θ (210, 240) of the funnel means (200) at the funnel
22 side (220), relative to a vertical, and of the charcoal discharge funnel means (230) at
23 the charcoal discharge funnel slope (240), in the preferred embodiment, will be
24 greater than approximately 45 degrees and are preferred at approximately 60
25 degrees. Both the funnel means and the charcoal discharge funnel means (230) are
26 primarily inverted conical in structure. Other cross sections will be equivalent as
27 will be appreciated by those of ordinary skill in the funnel arts.

28 The high temperature of collecting charcoal at the charcoal removal system
29 (40) and charcoal collection means (41) provides heat to be captured by introduction
30 of a charcoal heat exchanger means (260) provided, in the preferred embodiment by
at least one tube (262) penetrating the charcoal collection means (41) arena via heat

1 *exchanger ports (264) at the charcoal removal system wall (42).*

2

3 While a preferred embodiment of the present invention has been shown and
4 described, it will be apparent to those skilled in the art that many changes and
5 modifications may be made without departing from the invention in its broader
6 aspects. The appended claims are therefore intended to cover all such changes and
7 modifications as fall within the true spirit and scope of the invention.
